

POINTING DEVICE WITH FLEXIBLE SHAPE

Abstract

A pointing device includes a housing, a main body and an input section. The housing contains an upper cover and two extending arms, which extended from the upper cover. The main body is housed under the upper cover and located between the two extending arms of the housing. The input section is placed on the front half of the main body for generating (inputting) key signals. The front half (the input section) and the back half of the main body form a smooth surface.
